IMPORTANT NOTE

Before using the data contained in this report, you are strongly recommended to look at the following documents:

1. Methodology

This provides information about the analysis technique used and gives advice on the meaning of the results.

2. Data sources

This gives information about the number of plants examined, the date when the data were collected and information about up-stream operations.

In addition, you can also download data sets for most of the upstream operations used in this report. All of these documents can be found at: www.plasticseurope.org.

STEAM PRODUCTION.....	4
ECO-PROFILE OF STEAM.....	5

STEAM PRODUCTION

Steam is the principal carrier of thermal energy employed in almost all chemical processes. In all eco-profile calculations site-specific steam data have been used wherever possible. However, there are instances where details of the steam plant are not known and in yet other instances there are plants that import steam from off-site sources. It is therefore essential to have a data set for industrial steam production that can be used in these cases.

During the last decade or so details have been collected for over 200 different steam plants and these have been used to produce an 'average'.

There are however a number of points to be borne in mind.

1. The commonest way of producing steam is using the fossil fuels, coal, oil and gas. However, for economic reasons, many industrial boilers use low grade fuels so that the overall energy efficiency can be very variable.
2. In countries where there is a high proportion of hydro-power or nuclear power, steam may be generated using predominantly electricity.
3. Steam is often produced by waste incineration plant. Since the purpose of such plant in the chemical industry is primarily the efficient destruction of unwanted chemicals, steam production is only a secondary concern. As a result, the efficiency of such plant can often appear to be very low.
4. The feed water to steam plant can make a significant difference to overall efficiency. For example, if steam condensate is recovered or if the boiler feed water is pre-heated using waste heat from elsewhere, then steam production efficiency is boosted.
5. It is important to remember that for centrally operated steam plants on a site, the overall site efficiency may be more important than the efficiency of the steam delivered to a single operation.
6. Many plants practise steam and electricity co-generation. Depending on priorities, some of these plants can appear to be very efficient while others appear very inefficient
7. In times of change, steam plants can become inefficient. Often a facility may have been set up at a time when it was feeding several production units. But if some of these production units cease operation, then the steam plant may well be operating below its optimum performance.

8. Steam distribution also leads to losses. These losses are commonly in the range of 2% to 5% of the steam fed into the system.

ECO-PROFILE OF STEAM

Table 1 shows the gross or cumulative energy to produce 1 kg of steam and Table 2 gives this same data expressed in terms of primary fuels. Table 3 shows the energy data expressed as masses of fuels. Table 4 shows the raw materials requirements and Table 5 shows the demand for water. Table 6 shows the gross air emissions and Table 7 shows the corresponding carbon dioxide equivalents of these air emissions. Table 8 shows the emissions to water. Table 9 shows the solid waste generated and Table 10 gives the solid waste in EU format.
